Abstract

We pursue the possibility of the scenario in which the Higgs field is identified with the extra-space component of a bulk gauge field. The space-time we take is $M^4 \otimes S^1/Z_2$. We show that a non-trivial Z_2 -parity assignment allows some of the extra-space component to have radiatively induced VEV, which strongly modifies the mass spectrum and gauge symmetry of the theory, realized by orbifolding. In particular we investigate the dynamical mass generation of zero-mode fermion and spontaneous gauge symmetry breaking due to the VEV. The gauge theories we adopt are a prototype model $SU(2)$ and $SU(3)$ model, of special interest as the realistic minimal scheme to incorporate the standard model $SU(2) \times U(1)$.

1 Introduction

One of the long standing issues in the particle physics is the hierarchy problem. Conventional wisdom to solve the problem in four dimensional scheme is to rely on the supersymmetry. Recently it has been realized that alternative solutions are possible once we extend our space time [1, 2, 3]. The authors of [1, 2] adopted higher dimensional gravity theories, and aimed to solve the hierarchy problem between M_{pl} and M_W , invoking to large extra dimension [1], or to the “warp factor” appearing in the non-factorizable AdS_5 space-time with 3-branes[2], though the hierarchy was discussed at the classical level. The approach taken in [3] is a bit different: it deals with higher dimensional (bulk) gauge theories where the Higgs field is identified with the extra-space component of gauge field, and the main concern was the hierarchy problem at the quantum level. It has been shown that the summation of all Kaluza-Klein modes, inevitable to preserve the higher dimensional gauge symmetry, provides finite calculable Higgs mass, without suffering from the quadratic divergence [3]. See also [4, 5, 6, 7] for recent related development in various contexts, utilizing the finite Higgs mass due to the K-K mode sum.

In this paper we pursue the possibility of the bulk gauge theory, with the Higgs field being identified with the extra-space component. This type of scenario has a remarkable feature that all interactions of the Higgs field are uniquely determined by the gauge principle. Thus we may hope that all arbitrariness coming from the presence of Higgs in the Standard Model may be removed. On the other hand, as the theory is so restrictive, to achieve desirable pattern of gauge symmetry breaking and observed mass spectrum is not easy. Another well-known serious problem concerning matter fields in bulk theories is that to get massless chiral fermions is difficult, in general. Namely, we easily get mirror fermions with opposite chirality and the same quantum number with known quarks and leptons, which easily form massive Dirac particles with the ordinary matter.

An interesting and powerful tool to solve these problems has been proposed [8, 9] in the framework of bulk gauge theory with orbifold S^1/Z_2 as its extra-space. (See [10, 11] for other approaches based on localized fields on topological defects.) The key ingredient is that, in non-Abelian theories, we can assign non-trivial Z_2 -parities for fields to form an irreducible repr. of the gauge group. For instance in D=5 $SU(2)$ gauge theory, the theory is invariant under the Z_2 transformations of doublet fermion ψ , gauge fields $A_\mu (\mu = 0-3)$ and A_y (extra space component, to be identified with Higgs):

$$\psi \rightarrow P\gamma_5\psi, \quad A_\mu \rightarrow PA_\mu P, \quad A_y \rightarrow -PA_y P, \quad (1)$$

with $P^2 = I$ (I : 2×2 unit matrix). As an example let P be $\text{diag}(1, -1)$. Then, only ψ_{1R}, ψ_{2L} ($\psi_{1,2}$ are upper and lower components of the doublet), A_μ^3 and A_y^1, A_y^2 ($1, 2, 3$: indices of adjoint repr.) are even functions of 5-th space coordinate y , and therefore have

massless modes, when the theory is reduced to D=4 space-time. Thus as far as $1/R$ (R : the radius of S^1) is sufficiently large, the low energy effective 4-D theory has reduced gauge symmetry $U(1)$ and massless chiral fermions (without mirror partners). In ref.[8], utilizing this mechanism in $SU(5)$ GUT, the author has succeeded to solve so-called doublet-triplet splitting problem of 5-plet Higgs scalar, but at the classical level.

In this paper we show that such realized gauge symmetry and mass spectrum by the method of “ Z_2 orbifolding” illustrated above may be largely affected once the effect of the VEV of the extra-space component of gauge field $\langle A_y \rangle$, to be dynamically determined at quantum level, is included. Since the extra space S^1 has topologically non-trivial nature as a non-simply connected space, a constant background field $\langle A_y \rangle$ has non-trivial physical consequences, even though whose field strength is vanishing. As the typical example, the mechanism to break gauge symmetry spontaneously by a Wilson loop $W = P \exp(ig \oint \langle A_y \rangle dy)$ has been known as Hosotani mechanism [12]. We show that the VEV $\langle A_y \rangle$, allowed in non-Abelian theories with non-trivial Z_2 -parity assignment matrix P , generally causes not only spontaneous gauge symmetry breaking, but also the breaking of chiral symmetry, thus leading to dynamical mass generation for zero-mode fermions. At first sight the chiral symmetry seems never to be broken: the Z_2 symmetry acts as a chiral transformation, being accompanied by γ_5 , on fermion fields and this discrete symmetry seems to prevent fermions from developing any masses. We, however, should note that by a suitable choice of a non-trivial matrix P , we can arrange so that some pair of right- and left-handed Weyl fermions has identical Z_2 -parity (the example is the above-mentioned ψ_{1R} and ψ_{2L}), and A_y , which is associated with the “broken” generators connecting these Weyl fermions necessarily has even Z_2 -parity. Thus the VEV $\langle A_y \rangle$ is allowed and generates dynamical fermion masses of the order $g\langle A_y \rangle$, without any contradiction with the Z_2 symmetry. Another interesting issue to note is that the $\langle A_y \rangle$, in spite of the fact that it is radiatively induced, is proportional to $1/(gR)$ and therefore generates dynamical masses of the order $1/R$, which are just comparable to the masses obtained at the classical level by the orbifolding. The reason is rather easily understood as follows. The breaking of gauge and chiral symmetries are all controlled by the Wilson loop W . Just as in the case of the AB effect, when $W = I$, i.e. $g\langle A_y \rangle R = n$ (n : integer), corresponding to the quantization condition of “magnetic flux”, the theory is equivalent to the case of $\langle A_y \rangle = 0$. Thus the effective potential as the function of the constant background $\langle A_y \rangle$ is a periodic function with a period $1/(gR)$. The expected $\langle A_y \rangle$ is therefore expected to be of $O(1/(gR))$.

If $1/R$ is much larger than the weak scale M_W , such quantum effect raises the masses of some particles, which we wish to remain as the members of the weak scale physics, to $O(1/R)$, and the low energy effective theory obtained by the orbifolding is largely affected. For instance, the Higgs doublet, which remained massless after the “doublet-

triplet splitting” by orbifolding [8], may get a huge finite dynamical mass of $O(M_{GUT})$, which is undesirable from the view point of gauge hierarchy problem. (Note that in ref.[8], the Higgs scalar is not regarded as an extra-space component of gauge field and the Higgs mass-squared gets quadratically divergent quantum correction, anyway.) If, on the other hand, $1/R$ is comparable to M_W , this mechanism utilizing $\langle A_y \rangle$ may potentially provide a useful way to realize spontaneous gauge symmetry breaking together with the mass generation for ordinary matter fields through Yukawa coupling, which are essential ingredients needed in the 4-D Standard Model. We discuss, in addition to a prototype model $SU(2)$, $SU(3)$ model as a realistic minimal scheme to incorporate the standard model $SU(2) \times U(1)$, where such nice features of $\langle A_y \rangle$ manifest themselves.

2 Analysis at classical level and low energy effective theory

Our eventual goal should be to construct a realistic model of elementary particles, starting from a bulk gauge theory with matter fermions, which also propagate the bulk space-time, but without any higher dimensional scalars. The 4-dimensional (4D) scalar particle, the Higgs, should be identified with the extra space component of the bulk gauge field. The extra space is assumed to be an orbifold S^1/Z_2 , which plays key role for the construction. In this section the analysis is made at the classical level.

The theory we focus on is 5D $SU(N)$ Yang-Mills theory with N_f fermions belonging to the fundamental repr. of $SU(N)$. The space-time to work with is $M^4 \times S^1/Z_2$. We first leave N to be arbitrary for generality. The lagrangian reads as

$$\mathcal{L} = \sum_{f=1}^{N_f} \bar{\psi}^{(f)} i \gamma^M D_M \psi^{(f)} - \frac{1}{2} \text{tr}(F_{MN} F^{MN}) + \mathcal{L}_{gf} + \mathcal{L}_{gh}, \quad (2)$$

where we denote the gauge-fixing and ghost terms by $\mathcal{L}_{gf}$ and $\mathcal{L}_{gh}$. 5D space-time coordinates, gamma matrices and covariant derivative are denoted as $x^M = (x^\mu, y)$, $\Gamma^M \equiv (\gamma^\mu, i\gamma_5)$ ($\mu = 0 - 3$), and $D_M = \partial_M + igA_M$, respectively. ⁴

As the extra-space is the orbifold S^1/Z_2 , the lagrangian should be invariant under $y \rightarrow y + 2\pi R$ (R : the radius of S^1) and $y \rightarrow -y$. Because the theory under consideration has a continuous global symmetry $U(N)$, the invariance under $y \rightarrow y + 2\pi R$ does not necessitate periodic boundary conditions for fields and it is generally possible to impose a “twisted boundary conditions” $\psi(x, y + 2\pi R) = U\psi(x, y)$ and $A_M(x, y + 2\pi R) = UA_M(x, y)U^\dagger$

⁴ We use the metric $g_{MN} = \text{diag}(1, -1, -1, -1, -1)$ and the notation $A_M = \sum_a A_M^a T^a$ and $F_{MN} = \sum_a F_{MN}^a T^a$, where the generators of gauge group is normalized as $\text{tr}(T^a T^b) = \frac{1}{2} \delta_{ab}$.

where U is a y -independent unitary matrix.⁵ Similarly the following “twisted” identification under the Z_2 -parity transformation is possible [8],

$$\psi^{(f)}(x, -y) = \gamma_5 P \psi^{(f)}(x, y); \quad A_\mu(x, -y) = P A_\mu(x, y) P, \quad A_y(x, -y) = -P A_y(x, y) P. \quad (3)$$

The matrix P is a constant unitary matrix with a condition $P^2 = I$ (I : $N \times N$ unit matrix), which also imply that P is hermitian.⁶ Let us note that bare mass term $\bar{\psi}^{(f)} \psi^{(f)}$ is incompatible with the Z_2 -parity symmetry, irrespectively of the choice of P .

For the “twisted” boundary condition to be consistent with the Z_2 symmetry, a consistency condition

$$UPU = P. \quad (4)$$

should be imposed. Actually if we further utilizes the freedom of a local gauge transformation with gauge parameter, linear in y , the twisted boundary condition can be removed except for a $U(1)$ factor. Namely, writing U as $U = e^{i\phi} \exp(i\theta^a T^a)$, a gauge transformation,

$$\begin{aligned} \psi^{(f)} &\rightarrow \psi^{(f)'} = \exp(-i \frac{\theta^a T^a}{2\pi R} y) \psi^{(f)}, \\ A_M &\rightarrow A'_M = \exp(-i \frac{\theta^a T^a}{2\pi R} y) A_M \exp(i \frac{\theta^a T^a}{2\pi R} y) + \delta_M^y \frac{\theta^a}{2\pi g R} \cdot T^a, \end{aligned} \quad (5)$$

makes the fields $\psi^{(f)'}$, A'_M satisfy periodic boundary condition, up to an overall $U(1)$ phase factor, i.e. $\psi^{(f)'}(x, y + 2\pi R) = e^{i\phi} \psi^{(f)'}(x, y)$. The remaining phase factor, $U = e^{i\phi} \cdot I$, however, is incompatible with the consistency condition (4), unless $e^{i\phi} = \pm 1$. Thus we can assume $U = I$, periodic boundary condition, without loss of generality⁷, though such “large gauge transformation” should be compensated by a constant shift of the background field, $A_y^a \rightarrow A_y^a + \theta^a / (2\pi g R)$. Note that since S^1 is non-simply connected space, such constant background is physically meaningful and should be determined dynamically at quantum level, as we will see below. Further using a remaining freedom of global $U(N)$ transformation the matrix P always can be diagonalized. (Recall that P is hermitian.) Thus without loss of generality we can set $P = \text{diag}(1, \dots, 1, -1, \dots, -1)$.

In the rest of this section, we will study at the classical level how the choice of Z_2 -parity matrix P strongly affects the mass spectrum of bulk fields, thus determining the structure of the low energy effective theory.

⁵Strictly speaking, the theory also has a global symmetry $U(N_f)$ among N_f flavors, orthogonal to $U(N)$. However, we will not consider the twisting associated with $U(N_f)$, since it cannot be reduced to any constant background of extra space component of gauge field and therefore is not dynamically determined.

⁶We again ignore the twisting associated with $U(N_f)$.

⁷Another possibility $U = -I$ is not of our interest, as it forbids the presence of fermion zero mode.

2.1 SU(N) gauge theory with trivial Z₂-parity assignment

The first example is the case of trivial Z₂-parity matrix, $P = I$. Each field therefore has the following Z₂-parity:

$$A_\mu^a(x, -y) = A_\mu^a(x, y), \quad A_y^a(x, -y) = -A_y^a(x, y), \quad \psi_j(x, -y) = \gamma_5 \psi_j(x, y) \quad (6)$$

where $a=1,2,\dots,N^2-1$, and $j = 1$ to N . Flavor index f is suppressed for a while till it becomes necessary. To be consistent with these parity assignment, the gauge parameter ω^a should behave as

$$\omega^a(x, -y) = \omega^a(x, y) (= \omega^a(x, y + 2\pi R)). \quad (7)$$

Thus for all indices a four-dimensional gauge transformation with gauge parameter, independent of y , is allowed, and full gauge symmetry SU(N) remains in the 4D low energy effective theory. In fact the above parity assignment allows all A_μ^a to have zero(y -independent)-modes $A_\mu^{a(0)}(x)$ and they all remain massless in the reduced 4 D space-time. On the other hand we learn that the zero-modes of A_y^a are absent. Thus if excited K-K modes with masses n/R ($n \neq 0$) are regarded to decouple from the low energy world, the 4D low energy effective theory has no scalar field.

Concerning fermions, because of the presence of γ_5 in the Z₂ transformation, we know only the right-handed components have zero-modes, irrespectively of j . More explicitly, in the 2-component notation of Weyl fermion, each ψ_j can be expanded in Fourier series as

$$\psi_j(x, y) = \frac{1}{\sqrt{2\pi R}} \begin{pmatrix} u_{j,R}^{(0)}(x) + \sum_{n=1}^{\infty} u_{j,R}^{(n)}(x) \sqrt{2} \cos \frac{ny}{R} \\ \sum_{n=1}^{\infty} u_{j,L}^{(n)}(x) \sqrt{2} \sin \frac{ny}{R} \end{pmatrix}. \quad (8)$$

Thus the reduced 4D low energy effective theory is SU(N) gauge theory containing a full multiplet of gauge field $A_\mu^{(0)}(x)$ and a full multiplet of massless Weyl fermion of the same chirality $\psi_R^{(0)}(x)$, but without any scalar (Higgs) field.

2.2 SU(N) gauge theory with non-trivial Z₂-parity assignment

Next we discuss the case of non-trivial Z₂-parity assignment, with P not being proportional to I ; $P = \text{diag}(1, \dots, 1, -1, \dots, -1)$ with N_+ elements of 1 and N_- elements of -1 ($N_+ + N_- = N$; $N_+, N_- \geq 1$). If $[T^a, P] = 0$, $PT^aP = T^a$ and the associated gauge fields A_μ^a have zero-modes. Thus this choice of P breaks the gauge symmetry as

$$G = \text{SU}(N) \rightarrow H = \text{SU}(N_+) \otimes \text{SU}(N_-) \otimes \text{U}(1).$$

Note that the rank of the gauge group is not reduced. For a special case of $N_+, N_- = 1$, SU(1) should be just ignored.

Accordingly, zero-modes, remaining in low energy 4D effective theory is the following:

$$A_\mu^{a(0)} (a \in H); \quad A_y^{a(0)} (a \in G/H); \quad \psi_{jR}^{(0)} (j = 1 \text{ to } N_+), \quad \psi_{jL}^{(0)} (j = N_+ + 1 \text{ to } N). \quad (9)$$

We also note that zero-modes of gauge parameters ω^a appear only for $a \in H$, to be consistent with the remaining gauge symmetry.

In contrast to the case of $P = I$, now fermion zero-modes have both chiralities, and once $A_y^{a(0)}$ ($a \in G/H$), connecting Weyl fermions with different chiralities, develop non-vanishing VEV, these Weyl fermions will form a massive Dirac particle, as we will see in the following section for the details. The dynamical masses are produced through the 5D gauge interaction (4D Yukawa coupling),

$$ig\bar{\psi}\gamma_5\langle A_y^{a(0)}\rangle T^a\psi \quad (a \in G/H). \quad (10)$$

3 One-loop effective potential and the Hosotani mechanism in bulk gauge theories with non-trivial Z_2 -parity assignment

In this section we discuss how the dynamical fermion mass generation and spontaneous gauge symmetry breaking is realized via the radiatively induced VEV of A_y , i.e. the Hosotani mechanism [12, 13]. As has been already pointed out, in bulk gauge theories with extra orbifold space, such mechanism is possible only for the case with non-trivial Z_2 -parity assignment.

The bulk gauge theories we consider here are $SU(2)$ gauge theory, as a prototype model, and $SU(3)$ model, which is quite interesting in the sense that it provides realistic minimal framework to incorporate the standard model $SU(2) \times U(1)$.

The VEV of A_y is a finite calculable quantity, which is determined by the minimization of the one-loop induced effective potential as the function of constant background field $\langle A_y \rangle \equiv B_y$; we utilize background field method.

It is convenient to work with a gauge-fixing term for quantum fluctuation $\tilde{A}_M$, which uses gauge covariant derivative concerning the background field B_M , $\frac{1}{\xi}\text{tr}(D_M\tilde{A}^M)^2$, $D_M\tilde{A}^M = \partial_M\tilde{A}^M + ig[B_M, \tilde{A}^M]$ in the Feynman-'t Hooft gauge, $\xi = 1$.

3.1 $SU(2)$ model

We first take the $SU(2)$ bulk gauge theory with $P = \text{diag}(1, -1)$, as the prototype model with non-trivial Z_2 -parity assignment. At the classical level, the gauge symmetry is broken by the orbifolding:

$$G = SU(2) \rightarrow H = U(1), \quad (11)$$

where the remaining U(1) is due to the generator T^3 . The zero-modes, remaining in low energy 4D effective theory is the following:

$$A_\mu^{3(0)}; \quad A_y^{1,2(0)}; \quad \psi_{1R}^{(0)}, \quad \psi_{2L}^{(0)}. \quad (12)$$

Thus only $A_y^{1,2(0)}$ may develop VEV, i.e. $B_y^a = (B_y^1, B_y^2, 0)$. Thanks to the remaining global U(1) symmetry, we can always put this into the form of $B_y^a = (B_y^1, 0, 0)$. The 4D mass-squared operator $D_y D^y$ for the fields in the adjoint repr. under this background is

$$[D_y D^y]_{ab} = \begin{pmatrix} \partial_y \partial^y & 0 & 0 \\ 0 & \partial_y \partial^y - g^2 B_y^1 B^{y1} & -2g B^{y1} \partial_y \\ 0 & 2g B^{y1} \partial_y & \partial_y \partial^y - g^2 B_y^1 B^{y1} \end{pmatrix}, \quad (13)$$

where $a, b = 1, 2, 3$ are adjoint indices. Since this operator does not mix different K-K modes, we can diagonalize this operator separately for each K-K mode n . For $n \neq 0$ ($n > 0$), the matrix elements of the operator is easily obtained by using the basis of orthonormal functions $\frac{1}{\sqrt{\pi R}} \cos(\frac{n}{R}y)$ for $a, b = 3$, and $\frac{1}{\sqrt{\pi R}} \sin(\frac{n}{R}y)$ for $a, b = 1, 2$:

$$\begin{pmatrix} \frac{n^2}{R^2} & 0 & 0 \\ 0 & \frac{n^2}{R^2} + \frac{\alpha^2}{R^2} & 2\frac{\alpha n}{R^2} \\ 0 & 2\frac{\alpha n}{R^2} & \frac{n^2}{R^2} + \frac{\alpha^2}{R^2} \end{pmatrix}, \quad (14)$$

where $\alpha \equiv g B_y^1 R$. The eigenvalues are readily known to be $\frac{n^2}{R^2}$, $\frac{(n+\alpha)^2}{R^2}$, $\frac{(n-\alpha)^2}{R^2}$. For the zero-mode $n = 0$, only $A_\mu^{3(0)}$ with 4D mass-squared $\frac{\alpha^2}{R^2}$ exists. We note that 4D vector fields A_μ and F.-P. ghosts have the same Z_2 -parity assignment, and the effect of the ghosts is just to reduce the degree of the polarization to the physical one, $4 \rightarrow 2$. Thus, combining the contributions from both sectors of zero and non-zero modes, we obtain the contribution of 4D vector and ghost fields,

$$V_{eff}^{v+g} = \frac{1}{2\pi R} \int \frac{d^4 p_E}{(2\pi)^4} \frac{1}{2} \cdot 2 \left[\sum_{n=1}^{\infty} \log(p_E^2 + \frac{n^2}{R^2}) + \sum_{n=-\infty}^{\infty} \log(p_E^2 + (\frac{n-\alpha}{R})^2) \right], \quad (15)$$

where p_E is Euclidean momentum. In the case of 4D scalar A_y , the mass-squared matrix is the same as those of A_μ and F.-P. ghosts, except that the Z_2 -parity assignment is just opposite. Thus for zero-modes $A_y^{1,2(0)}$, the mass-squared matrix is $\text{diag}(0, \frac{\alpha^2}{R^2})$. The contribution of A_y is thus given as

$$V_{eff}^s = \frac{1}{2\pi R} \int \frac{d^4 p_E}{(2\pi)^4} \frac{1}{2} \cdot 1 \left[\sum_{n=0}^{\infty} \log(p_E^2 + \frac{n^2}{R^2}) + \sum_{n=-\infty}^{\infty} \log(p_E^2 + (\frac{n-\alpha}{R})^2) \right]. \quad (16)$$

Summing up these two contributions, we obtain the one-loop induced effective potential from 4D vector, ghost and scalar fields,

$$V_{eff}^{v+g+s} = \frac{1}{2\pi R} \int \frac{d^4 p_E}{(2\pi)^4} \times \left(\frac{1}{2} \cdot 3 \left[\sum_{n=1}^{\infty} \log(p_E^2 + \frac{n^2}{R^2}) + \sum_{n=-\infty}^{\infty} \log(p_E^2 + (\frac{n-\alpha}{R})^2) \right] + \frac{1}{2} \log p_E^2 \right). \quad (17)$$

By a suitable regularization method and subtracting irrelevant α -independent part we obtain a finite result [12].

$$V_{eff}^{v+g+s} = -3C \sum_{n=1}^{\infty} \frac{1}{n^5} \cos(2\pi n\alpha), \quad (18)$$

where $C = \frac{3}{128\pi^7 R^5}$.

On the other hand, the mass-squared operator for fermions belonging to a fundamental repr. is

$$[D_y D^y]_{ij} = \begin{pmatrix} \partial_y \partial^y + \frac{\alpha^2}{4R^2} & -i\frac{\alpha}{R} \partial_y \\ -i\frac{\alpha}{R} \partial_y & \partial_y \partial^y + \frac{\alpha^2}{4R^2} \end{pmatrix}. \quad (19)$$

For non-zero K-K modes, the matrix in the basis of Dirac fermion ψ_1, ψ_2 reads as

$$[D_y D^y]_{ij} = \begin{pmatrix} \frac{n^2}{R^2} + \frac{\alpha^2}{4R^2} & -i\frac{\alpha n}{R^2} \gamma_5 \\ i\frac{\alpha n}{R^2} \gamma_5 & \frac{n^2}{R^2} + \frac{\alpha^2}{4R^2} \end{pmatrix}, \quad (20)$$

whose eigenvalues are $\frac{(n+\frac{\alpha}{2})^2}{R^2}$ and $\frac{(n-\frac{\alpha}{2})^2}{R^2}$, each having 4-fold degeneracy. The zero-mode is composed of two Weyl fermions ψ_{1R} and ψ_{2L} and the mass-squared matrix in this basis reads as

$$[D_y D^y]_{ij} = \begin{pmatrix} \frac{\alpha^2}{4R^2} & 0 \\ 0 & \frac{\alpha^2}{4R^2} \end{pmatrix}. \quad (21)$$

We thus find the contribution of N_f fermions to the effective potential

$$V_{eff}^f = -N_f \cdot \frac{1}{2\pi R} \int \frac{d^4 p_E}{(2\pi)^4} \frac{1}{2} \cdot 4 \left[\sum_{n=-\infty}^{\infty} \log(p_E^2 + (\frac{n-\alpha/2}{R})^2) \right]. \quad (22)$$

The relevant finite part is

$$V_{eff}^f = 4N_f C \sum_{n=1}^{\infty} \frac{1}{n^5} \cos(\pi n\alpha). \quad (23)$$

Combining all contributions, we get the effective potential

$$V_{eff}(\alpha) = V_{eff}^{v+g+s} + V_{eff}^f = C \sum_{n=1}^{\infty} \frac{1}{n^5} [-3 \cos(2\pi n\alpha) + 4N_f \cos(\pi n\alpha)]. \quad (24)$$

As we learn from Fig.1, though for pure Yang-Mills case $N_f = 0$ the theory has two degenerate vacua at $\alpha = 0$ and 1, including fermions the global minimum is located at $\alpha = 1$. We thus obtain VEV $B_y^1 = 1/(gR)$, which may spontaneously break gauge symmetry (note that $[T^3, B_y] \neq 0$) and simultaneously generates dynamical fermion mass for the zero mode. Concerning the spontaneous gauge symmetry breaking, however, we find that actually the U(1) symmetry is not broken by the VEV B_y . This is because what we should care about is the commutator of the Wilson-loop W . We note $\langle W \rangle = P \exp(ig \oint B_y dy) = \exp(ig B_y^1 \frac{\sigma_1}{2} (2\pi R)) = \exp(i\pi \sigma_1) = -I$. Thus $[T^3, \langle W \rangle] = 0$ and the

Figure 1: The one-loop effective potential in the unit of $C = \frac{3}{128\pi^7 R^5}$ as a function of $\alpha = gB_y^1 R$ in the SU(2) model: (a) The contribution from gauge-ghost system, V_{eff}^{v+g+s} . (b) The contribution from fermions V_{eff}^f .

gauge symmetry is not spontaneously broken. We can explicitly confirm this from the mass-squared matrix of A_μ . Though the mass-squared of the zero mode $A_\mu^{3(0)}$ is raised to $\frac{1}{R^2}$ due to the VEV, we learn that the mass-squared matrix for $n = 1$ sector now has zero eigenvalue: $\frac{(1-1)^2}{R^2} = 0$ for $\alpha = 1$.

On the other hand, concerning fermion masses, what matters is whether $\langle W \rangle = I$ or not. As $\langle W \rangle = -I$, we expect that fermions obtain a dynamical Dirac mass. It is actually the case and we have a mass term for the zero mode (for every flavor index f)

$$ig\psi^{(0)}i\gamma_5 B_y^1 T^1 \psi^{(0)} = -i\frac{g}{2}B_y^1 [\psi_{1R}^{(0)}\psi_{2L} - \psi_{2L}^{(0)}\psi_{1R}]. \quad (25)$$

Thus the generated dynamical mass is $\frac{g}{2}B_y^1 = \frac{1}{2R}$. In fact the mass-squared matrix for the fermion zero-mode, discussed above, has eigenvalue $\frac{1}{4R^2}$ with $\alpha = 1$, while the matrix for $n = 1$ mode also has an eigenvalue $\frac{(1-\frac{1}{2})^2}{R^2}$, but no 0 eigenvalue.

The same mechanism is known to work for matter scalar fields as well, as long as they belong to a fundamental repr., $(\phi_1, \phi_2)^T$. The same mass-squared matrix as the case of fermions (except for spin degree of freedom and γ_5 factor) is obtained for $n \neq 0$ modes, though in the case of scalar only ϕ_1 is allowed to have a zero-mode, whose mass-squared eigenvalue is again dynamically raised to $\frac{1}{4R^2}$. The same mechanism is expected to be operative even in the case of 5-plet Higgs fields of SU(5) GUT, and the doublet-triplet splitting, realized at the classical level [8], is expected to be spoilt once quantum effect is switched on, as the doublet scalar (corresponding to ϕ_1^0 in our model) is expected to get radiatively generated mass of the order $\frac{1}{R} \sim M_{GUT}$.

In addition, A_y^1 itself, which we identified with the Higgs, also obtain the finite mass [3]

$$m_{A_y}^2 = [g^2 R^2 \frac{\partial^2 V_{eff}(\alpha)}{\partial \alpha^2}]_{\alpha=1} = \frac{9g^2}{128\pi^5 R^3} (4 + N_f) \zeta(3) = \frac{9g_4^2}{64\pi^4 R^2} (4 + N_f) \zeta(3), \quad (26)$$

where $\zeta(z)$ is the Riemann's zeta-function and $g_4 = g/(\sqrt{2\pi R})$ is the 4D gauge coupling.

3.2 SU(3) model

One may naively expect that a realistic model incorporating the standard model can be constructed just putting the gauge theory $SU(2) \otimes U(1)$ in the bulk. We, however, immediately notice it is not the case; 4D scalar A_y , to be identified with Higgs field, belongs to the adjoint repr. 3 of $SU(2)$, but not to the doublet, which the Higgs should belong to. Such problem is evaded once we enlarge the gauge group a little bit. The possible minimal extension is the $SU(3)$ bulk gauge model. Let us note that the adjoint of $SU(3)$ decomposes into the repr.s of subgroup $SU(2)$ as $8 \rightarrow 3 + 2 + 2 + 1$.

The $SU(3)$ symmetry can be broken by orbifolding into that of the standard model, once we adopt a non-trivial Z_2 -parity assignment $P = \text{diag}(1, -1, -1)$:

$$G = SU(3) \rightarrow H = SU(2) \otimes U(1). \quad (27)$$

There is a bonus; among $3 + 2 + 2 + 1$ of A_y , only the doublet, belonging to G/H , has zero-mode, which we identify with our Higgs: $H = (A_y^{1(0)} + iA_y^{2(0)}, A_y^{4(0)} + iA_y^{5(0)})^t$. More explicitly the remaining zero-modes are

$$A_\mu^{a(0)} \quad (a = 3, 6, 7, 8); \quad A_y^{a(0)} \quad (a = 1, 2, 4, 5); \quad \psi_{1R}^{(0)}, \quad \psi_{2L}^{(0)}, \quad \psi_{3L}^{(0)}. \quad (28)$$

It turns out that the remaining fields are just what we need in the standard model. Interestingly, the members of triplet fermion is known to have quantum numbers to be identified with quarks [14].

We now discuss the spontaneous gauge symmetry breaking and dynamical fermion mass generation due to the VEV of A_y , i.e. the Hosotani mechanism. The procedure itself is the same as in the case of $SU(2)$, though the calculation becomes a little more complicated. So we just outline the results below. We first note that, utilizing the global $SU(2) \otimes U(1)$ symmetry, we can always set the VEV in the form of $B_y^a = (B_y^1, 0, 0, 0, 0, 0, 0, 0)$.

Following the procedure explained in the $SU(2)$ model, including the zero-mode contributions properly, we obtain the contribution from the gauge sector, i.e. 4D vector, scalar and ghost fields:

$$\begin{aligned} V_{eff}^{g+gh+s} &= \frac{1}{2\pi R} \int \frac{d^4 p_E}{(2\pi)^4} \times \frac{1}{2} \cdot 3 \\ &\cdot \sum_{n=-\infty}^{\infty} [\log(p_E^2 + \frac{n^2}{R^2}) + \log(p_E^2 + (\frac{n-\alpha}{R})^2) + 2\log(p_E^2 + (\frac{n-\alpha/2}{R})^2)]. \end{aligned} \quad (29)$$

Then the finite α -independent part is calculated to be

$$V_{eff}^{g+gh+s} = -3C \sum_{n=1}^{\infty} \frac{1}{n^5} (\cos(2\pi n\alpha) + 2\cos(\pi n\alpha)). \quad (30)$$

Figure 2: The contribution to the effective potential from the gauge-ghost system in the SU(3) model, in the unit of $C = \frac{3}{128\pi^7 R^5}$ as a function of $\alpha = gB_y^1 R$.

The contribution from the triplet fermions can be regarded as the sum of the contributions from ψ_1 and ψ_2 under the background B_y^1 , which is just the same as in the SU(2) model, and ψ_3 without the influence of B_y^1 . Thus the contribution from the fermion system can be rather trivially evaluated:

$$V_{eff}^f = -N_f \cdot \frac{1}{2\pi R} \int \frac{d^4 p_E}{(2\pi)^4} \frac{1}{2} \cdot 4 \left[\sum_{n=-\infty}^{\infty} \log[(p_E^2 + (\frac{n - \alpha/2}{R})^2 + \frac{1}{2} \log(p_E^2 + \frac{n^2}{R^2})] \right]. \quad (31)$$

The finite α -independent part is calculated to be the same as in the case of SU(2) (shown in Fig.1-(b)):

$$V_{eff}^f = 4N_f C \sum_{n=1}^{\infty} \frac{1}{n^5} \cos(\pi n \alpha). \quad (32)$$

The sum of all contributions to the effective potential now reads as

$$V_{eff} = -3C \sum_{n=1}^{\infty} \frac{1}{n^5} [\cos(2\pi n \alpha) + 2 \cos(\pi n \alpha)] + 4N_f C \sum_{n=1}^{\infty} \frac{1}{n^5} \cos(\pi n \alpha). \quad (33)$$

Now having the effective potential, we are ready to discuss the VEV and the Hosotani mechanism. It is interesting to note that the pattern of gauge symmetry breaking crucially depends on the number N_f of triplet fermions, in contrast to the case of the SU(2) model. For pure Yang-Mills theory, we see from Fig.2 that the vacuum is located only at $\alpha = 0$. However, as N_f increases, as Fig.1-(b) suggests, the local minimum at $\alpha = 1$ becomes deeper. Thus for sufficient number of fermions we expect non-vanishing VEV. In fact, the difference of the depths at two local minima is given by

$$V_{eff}(\alpha = 0) - V_{eff}(\alpha = 1) = 4C \sum_{n=1}^{\infty} \frac{1}{(2n+1)^5} (2N_f - 3). \quad (34)$$

Therefore, if N_f is less than two, the global minimum is at $\alpha = 0$ and the Hosotani mechanism does not work, though we get a ‘‘Higgs’’ mass-squared

$$m_{A_y}^2 = \frac{3g_4^2}{32\pi^4 R^2} (9 - N_f) \zeta(3). \quad (35)$$

On the other hand, for $N_f \geq 2$ the global minimum is at $\alpha = 1$, i.e. $B_y^1 = 1/(gR)$. In contrast to the case of SU(2) model, this VEV does break gauge symmetry spontaneously, but not into U(1):

$$\text{SU}(2) \otimes \text{U}(1) \rightarrow \text{U}(1) \otimes \text{U}(1). \quad (36)$$

This is because for $\alpha = 1$ the Wilson loop

$$W = \exp\left(ig \int_{-\pi R}^{\pi R} B_y^1 T^1\right) = \begin{pmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad (37)$$

does not commute with T^6, T^7 , but still commutes with T^3 and T^8 . This VEV also causes a dynamical fermion mass. It is easy to understand that the VEV $B_y^1 = 1/(gR)$ provides a Dirac mass term for the zero modes $\psi_{1R}^{(0)}$ and $\psi_{2L}^{(0)}$, just as in the case of SU(2) model,

$$ig\psi^{(0)\dagger}\gamma_5 B_y^1 T^1 \psi^{(0)} = -i\frac{g}{2}B_y^1 [\psi_{1R}^{(0)\dagger}\psi_{2L}^{(0)} - \psi_{2L}^{(0)\dagger}\psi_{1R}^{(0)}], \quad (38)$$

which gives a massive Dirac particle with dynamical mass $1/(2R)$, while $\psi_{3L}^{(0)}$ remains massless. In this case the Higgs mass-squared is given as

$$m_{A_y}^2 = \frac{9g_4^2}{128\pi^4 R^2} (5 + 2N_f)\zeta(3). \quad (39)$$

We summarize these results in Table 1.

	pattern of gauge symmetry breaking	dynamical fermion mass
$(N_f \leq 1)$	$\text{SU}(2) \otimes \text{U}(1) \rightarrow \text{SU}(2) \otimes \text{U}(1)$	0
$(N_f \geq 2)$	$\text{SU}(2) \otimes \text{U}(1) \rightarrow \text{U}(1) \otimes \text{U}(1)$	$\frac{1}{2R}$

Table 1: The pattern of gauge symmetry breaking and dynamical fermion mass

4 Conclusions and Remarks

In this paper we studied the Hosotani mechanism, i.e. spontaneous gauge symmetry breaking and dynamical mass generation of bulk fermions, in the bulk gauge models SU(2) and SU(3) on the space-time $M^4 \times (S^1/Z_2)$. In addition to the gauge fields, matter fermions belonging to the fundamental repr. were included. In these models extra-space component of a gauge field A_y is identified with a 4D scalar field, “Higgs”, i.e. gauge Higgs unification has been realized. The crucial ingredient is the non-trivial assignment of Z_2 -parity for the fields, forming an irreducible repr. of gauge group [8, 9]. The parity assignment, “orbifolding”, explicitly breaks the gauge symmetry and leads to a specific selection rule

of the zero-mode (massless) fields in a given repr. at the classical level. Then some of A_y , associated with broken generators, are assigned even parity and allowed to have zero-modes, which we identify with the Higgs, and generally develop non-vanishing VEV. The VEV $\langle A_y \rangle$ can be dynamically determined by the minimization of the radiatively induced effective potential. Such obtained VEV causes spontaneous breaking of gauge symmetry [12], which is left after the orbifolding, and/or generates dynamical masses for the zero-mode fermions (and Higgs itself [3]).

As the prototype model, we first discussed SU(2) model, and calculated the effective potential, by use of background field method, in order to fix the VEV. The generated VEV gave a Wilson loop $W = -I$, proportional to the unit matrix, thus leading to no spontaneous gauge symmetry breaking, while it gave a dynamical mass for doublet zero-mode fermion of the order $1/R$ (R : the radius of S^1), as $W \neq I$. Such dynamical mass generation was argued to occur very similarly for the matter scalars belonging to the fundamental repr.. Thus the doublet-triplet splitting realized by the non-trivial Z_2 -parity assignment in the SU(5) GUT [8] is expected to be spoilt by the induced huge dynamical mass for the doublet scalar of the order $1/R \sim M_{GUT}$.

As the candidate to provide a realistic model to incorporate the standard model SU(2) $\times$ U(1), we next discussed SU(3) model with a non-trivial Z_2 -parity assignment $P = \text{diag}(1, -1, -1)$. The orbifolding caused an explicit gauge symmetry breaking SU(3) $\rightarrow$ SU(2) $\times$ U(1), together with a specific selection rule of the zero-mode fermions. The resultant zero-modes of 4D vector, scalar and fermion fields are just what we need in the standard model, though some of matter fermion fields are still missing. In particular, we get a doublet 4D scalar, which is nothing but our Higgs field. We have shown that for sufficient number of matter fermions, the non-vanishing VEV of the Higgs doublet is radiatively generated. The induced VEV was argued to cause a spontaneous breaking, SU(2) $\times$ U(1) $\rightarrow$ U(1) $\times$ U(1) and dynamical Dirac mass for a pair of zero-mode Weyl fermions, in complete similarity with ordinary mass generation via Yukawa coupling in the standard model. The derived model has very characteristic matter contents and various properties, as we will discuss in our forthcoming paper for the detail [14]. In particular the triplet matter fermions turn out to have the same quantum numbers as those of quarks, $(d_R, u_L, d_L)^t$. This is in clear contrast to the ordinary 4D SU(3) unified gauge theory. In the 4D theory, the fermion triplet can be identified with $(e^+, \nu_e, e^-)_L^t$. Also the Higgs, providing the mass for the electron belongs to the repr. $3 \times 3 = \bar{3} + 6$, but not 8 of SU(3). The essential difference between our 5D SU(3) model and the 4D SU(3) model is the difference of the chirality assignment for each component of the triplet fermion, which originates from our non-trivial assignment of the Z_2 -parity in the orbifolding.

The SU(3) theory, however, still has some fundamental problems to be settled before

it becomes a realistic model. First it should be pointed out that the Hosotani mechanism [12] discussed in this paper did not lead to a reduction of the rank of the gauge group: $U(1) \times U(1)$ still has rank 2. In the forthcoming paper [14] we will demonstrate that to reduce the rank, necessary to realize $U(1)_{em}$, is possible once we introduce matter fields with adjoint repr.. We will also see, among other things, that suitably choosing the number of fermions belonging to fundamental and adjoint repr., we can realize a mild hierarchy between the mass scales generated by orbifolding and the Hosotani mechanism, which are, roughly speaking, both of the order $1/R$, as we discussed in the introduction. Such mild hierarchy is needed for the 2 step breaking, $SU(3) \rightarrow SU(2) \times U(1) \rightarrow U(1)$.

The bulk gauge theories, similar to the ones discussed in the present paper, have been already discussed by several authors in various context [7, 15], where, however, the dynamical fermion mass generation is not discussed and/or supersymmetry plays a crucial role.
